Abstract. Well-known cutaneous side effects of interferon (IFN)-alfa therapy include dry skin, pruritus, hair loss, and psoriasis. Presumably because of its potent immunomodulatory activity, the use of IFN-alfa has also led to the development of autoimmune diseases in susceptible individuals. Vitiligo, an autoimmune cutaneous disease, has been reported to occur during IFN-alfa therapy.

PFIC2 was confirmed in our patient through genetic testing, and a unique coexistence with psoriasis and vitiligo was noted. No clinical association regarding psoriasis or vitiligo to such disorders has been documented in the literature to our knowledge, and this article presents the first case of PFIC2 in the context of both psoriasis and vitiligo. The coexistence of psoriasis and vitiligo has been reported in the literature, although the association is uncommon.

The pathogenesis of pruritus in psoriasis is poorly known since the main cytokines involved in psoriasis are not known to be pruritogenic. The major concept of pruritus origin is focused on neurogenic inflammation, through the release of neuropeptides from nerve endings, in association with a modified innervation density in psoriasis as well as an abnormal functioning of the peripheral opioid system (22).

Treat your psoriasis. The best way to get rid of the itch is to treat psoriasis. Remove scale. Less scale often means less itchiness. Removing scale can also improve the results you get from itch-relieving products. To remove scale, you want to use medicine like salicylic acid. This helps soften the scale, so you can gently brush it away.

Vitiligo is characterized by the appearance of white patches of skin on different parts of the body as a result of the destruction of melanocytes. This may vary from one or two white spots on the skin to large areas of depigmentation. Vitiligo is not contagious. For some people, although not for everyone, the depigmentation is progressive.
